a benzodiazepine might be anticonvulsant but not. sedative. One of the most extensively studied benzodiazepine, inverse agonists has been Ro 15-4513, primarily because. of its reported ability to antagonise the central effects. of alcohol. There has been much debate as to the.

Classification of benzodiazepine receptor agonists, inverse agonists and antagonists using bicuculline in an in vitro test. The mechanism by which a substance that binds to the benzodiazepine receptor acts as an agonist, an inverse agonist (e.g. methyl-beta-carboline-3-carboxylate (beta-CCM) or an antagonist (e.g. Ro 15-1788) was investigated.

Benzodiazepine inverse agonists have the opposite effect to agonists i.e. are proconvulsant, anxiogenic etc. Such compounds have played a salient role in the characterization of the GABAa receptor complex, within which lies the benzodiazepine receptor binding site.

Diphenhydramine and Doxylamine: It is estimated that >60% of pharmacotherapy for insomnia is via nonpre-scription medications. 2 Diphenhydramine (e.g., Sominex) and doxylamine (e.g., Unisom SleepTabs) are first-generation antihistamines that work via competition with histamine at H 1 receptors as inverse agonists.

An agonist increases the activity of a receptor above its basal level, whereas an inverse agonist decreases the activity below the basal level. The efficacy of a full agonist is by definition 100%, a neutral antagonist has 0% efficacy, and an inverse agonist has < 0% (i.e., negative) efficacy.

Discontinuation after long-term benzodiazepine use leads to withdrawal syndrome, which is associated with inverse agonist receptor activity. Decreased activity of the GABA receptor complex after cessation is probably responsible for the occurrence of most abstinence symptoms (Salzman, 1998; Winstock, 2005).

DMCM (methyl-6,7-dimethoxy-4-ethyl-beta-carboline-3-carboxylate) is a drug from the beta-carboline family. It acts as a negative allosteric modulator of GABAA receptors, meaning that it causes the opposite effects to the benzodiazepine class of drugs.

Flumazenil, at doses lower than those that cause an enhancement, antagonizes the effect of benzodiazepine agonists and inverse agonists. This suggests that memory is modulated during acquisition by endogenous benzodiazepine receptor ligands: possibly the diazepam that was recently discovered in brain.

Rats were exposed to a two-layer drug discrimination procedure using the benzodiazepine (BZ) receptor inverse agonists N'-methyl-β-carboline-3-carboxamide (FG 7142) or methyl-6,7-dimethoxy-4-ethyl-β-carboline-3-carboxylate (DMCM). FG 7142 (30 mg/kg) failed to acquire discriminative stimulus control, although it did suppress responding.

The receptor to which benzodiazepine hypnosedatives and anticonvulsants bind was discovered and characterized in the late 1970s. Agonists and inverse agonists that act at various sites within the receptor complex have been identified. In addition, antagonists of the benzodiazepine receptor have been synthesised.
