Metabolic therapies treat the cause of cancer: the diseased mitochondria and the environmental factors that cause them to become diseased. Since the metabolic paradigm starting coming back into prominence around 2012 with Seyfried's Cancer as a Metabolic Disease, research has been piling up supporting these treatments.

Cancer is a metabolic disease, there is little doubt to that statement. Cancer is rarely a genetic disease, though often discussed as such. What genetic changes that do exist in cancer are likely the result of the metabolic dysfunction and poor adaptation for survival that results from a hypoxic environment.

While there is renewed interest in the energy metabolism of cancer cells, it is widely thought that the Warburg effect and the metabolic defects expressed in cancer cells arise primarily from genomic mutability selected during tumor progression [36 - 39].

Although cancer has historically been viewed as a disorder of proliferation, recent evidence has suggested that it should also be considered a metabolic disease. Growing tumors rewire their metabolic programs to meet and even exceed the bioenergetic and biosynthetic demands of continuous cell growth.
