Resilient Wood Construction Resists Wind, Weather, Seismic Forces & Moisture. Wood is the resilient choice for construction. Wood's strength combined with its ability to absorb stresses or impacts without weakening or degrading make wood a superior building material, especially in areas susceptible to severe weather conditions or seismic activity.

Indeed some steel structures are sufficiently light that seismic design is not critical. This is particularly the case for halls/sheds: they create an envelope around a large volume so their weight per unit surface area is low and wind forces, not seismic forces, generally govern the design.

Abstract: TDI researchers measured a wide range of performance indicators of CLT, both within a controlled laboratory setting and within occupied buildings outfitted with sensors. The goals were to generate monitoring protocols, acquire benchmark data about the holistic performance of CLT buildings (which will ultimately help define performance standards for CLT systems) and to explore how ...

The vertical structure of the MahaNakhon Tower is made of a central RC core wall of 23 x 23 m at the basement and is gradually reduced to 23 x 14 m to the top of the tower, providing structural stability to lateral loads such as wind and seismic action. The gravitational load is mostly supported by 12 megacolumns (constructed with 60 MPa

In a high seismic area, when a design earthquake hits a very stiff non deformable structure, the structure can experience a very large lateral force caused by the inertia of the building. This force in many instances can be several times the force that can be generated by the wind loading. Designing for Seismic Resistant Structures

Design for Wind or Seismic Resistant Structures

The lateral load mainly consist of seismic forces, wind load, mooring load, tsunami etc., amongst which the seismic force and the wind force are the common ones. The application of these forces and the behaviour of the structure when subjected to these forces varies.
